# 3-Way Temperature Control Valve - Model G, Version G

## Overview

AMOT G valves are 3-way control valves consisting of a heavy-duty rotary valve and either a quarter turn electric or pneumatic actuator. The valves provide a high degree of accuracy and repeatability for accurate temperature control and are equally accurate in mixing or diverting service over a wide flow range.

The heavy-duty rotor design provides tight temperature control without high maintenance requirements. The system is available in three standard control configurations: electric; pneumatic; and electro-pneumatic, offering flexibility for most requirements.

Some actuator options are designed and reinforced for vibration service and are qualified to Lloyd's Marine Requirements for shipboard service. Certain G Valve and actuator combinations can be directly mounted to reciprocating machinery such as diesel engines, without vibration isolation.

Standard G Valves are suitable for a variety of fluids such as water, water/glycol, sea water, lubricating and hydraulic oils. Optional body materials are available for services involving synthetic or fire resistant oils, deionized water and ammonia or freon in oil.

## Applications

### Mixing Applications

Lubricating oil temperature control is normally configured in a mixing application controlling the return temperature to the heat load. The temperature is normally measured as close as possible to the sump return.

### Diverting Applications

Jacket water cooling in diverting applications regulates the outlet coolant water temperature from a diesel or gas engine. The valve either sends water to a cooler or bypass loop, accurately maintaining the temperature.

The temperature is normally measured at the outlet from the heat source.

### Charge Air Temperature Control

The intercooler is used to cool high temperature turbo charger air.

In this application the G Valve regulates the flow of cooling water through an intercooler, increasing efficiency, enhancing performance and helping to meet today's environmental requirements.

## System Types (Electric)

For the electrically operated valves, a number of actuator options are available, which use an electric motor that rotates in either direction in response to the ON-OFF signals received. The motor drives a gearbox connected to the rotor shaft and turns the valve rotor clockwise or counter-clockwise, a maximum of 90 degrees. At the end of travel, limit switches are incorporated to isolate the electrical supply to the motor when the valve rotor has reached either end of the rotation. A feedback hall sensor is available on some actuators, providing position indication to the control system.

Most actuators are powered by an electric motor driving a worm-type gearbox. The worm gearbox prevents reverse drive due to the forces generated by fluid flow.

A thermal cutout is fitted preventing overheating. Limit switches at each end of stroke disconnect motor power when end stroke is reached. These can also be used for remote indication.

See page 12 for more information on the electric actuator options.

A typical electric valve system incorporates an electrically actuated three-way control valve with an electronic controller and temperature probe. The 8071D PID Controller can be either panel or wall mounted (see page 21 for more information). The system is completed with a temperature sensor type 8060 (see page 21 for details).

The electric G Valve system is simple to install with standard multicore cable and provides more accurate measurement and control than typical pneumatically operated systems.

## System Types (Pneumatic)

The pneumatic valve uses a spring return pneumatic actuator and positioner to control the rotation of the valve in response to an input signal for a pneumatic or electro-pneumatic control system. The pneumatic control system sends a pneumatic signal ranging from 0.21 to 1.03 bar (3 to 15 psi) to the actuator to correctly position the valve rotor to achieve the correct system temperature. The pneumatic control system usually consists of a P+I pneumatic controller, sensor and the necessary air supply conditioning equipment (regulators, filters and water traps).

The pneumatic actuator is a rugged, quarter turn, double piston actuator operating on a scotch yoke principle.

The actuator is fitted with spring return as standard allowing fail-safe configuration if necessary. It is also fitted with a valve positioner enabling accurate and repeatable movement. See page 13 for more information on the pneumatic actuator.

## Pneumatic System

The pneumatic valve system incorporates a pneumatically actuated three-way control valve with controller and integral temperature sensor, the SG80, which can be panel or wall mounted. For more information on the SG80, see page 23. The pneumatic G valve system is ideal when there is a lack of electricity or when a fail-safe system is needed.

## Electro-Pneumatic System

The electro-pneumatic valve system combines both electric and pneumatic technology, consisting of a pneumatically actuated three-way control valve with an electro-pneumatic converter, type 8064A (where available) or type 8064C. See pages 22 and 23 for more details.

The probe sends a resistance signal to the electronic controller, which in turn sends a 4 to 20mA signal to an I/P converter that converts this to a pneumatic signal.

The electro-pneumatic system combines the features and functionality of the AMOT electronic control system with the fail-safe action benefits of a pneumatically actuated valve.

Port Number Diagram

The unique construction of the AMOT G Valve provides total flexibility by allowing valve port position selections to most ideally suit application requirements. There are two main types of mode of operation: 90° rotor that allows either ports 1 or 3 to be selected as the common port; and 180° rotor that requires port 2 to be the common port.

For electrically actuated valves, the 'Start' and 'End' positions indicate valve movement with a change in input signal, as viewed from above (see diagram). On loss of signal the actuator is set up by default to stop in its current position.

For pneumatically actuated valves, the 'Start' and 'End' positions indicate valve movement with a change in input signal, as viewed from above (see diagram). On loss of signal the actuator is set up by default to return to its 'Start' position.

For 'Start' & 'End' input conditions, see table below.

## Viscosity Correction

**Example:**

From the graph below:

100 cSt = correction factor of 0.68

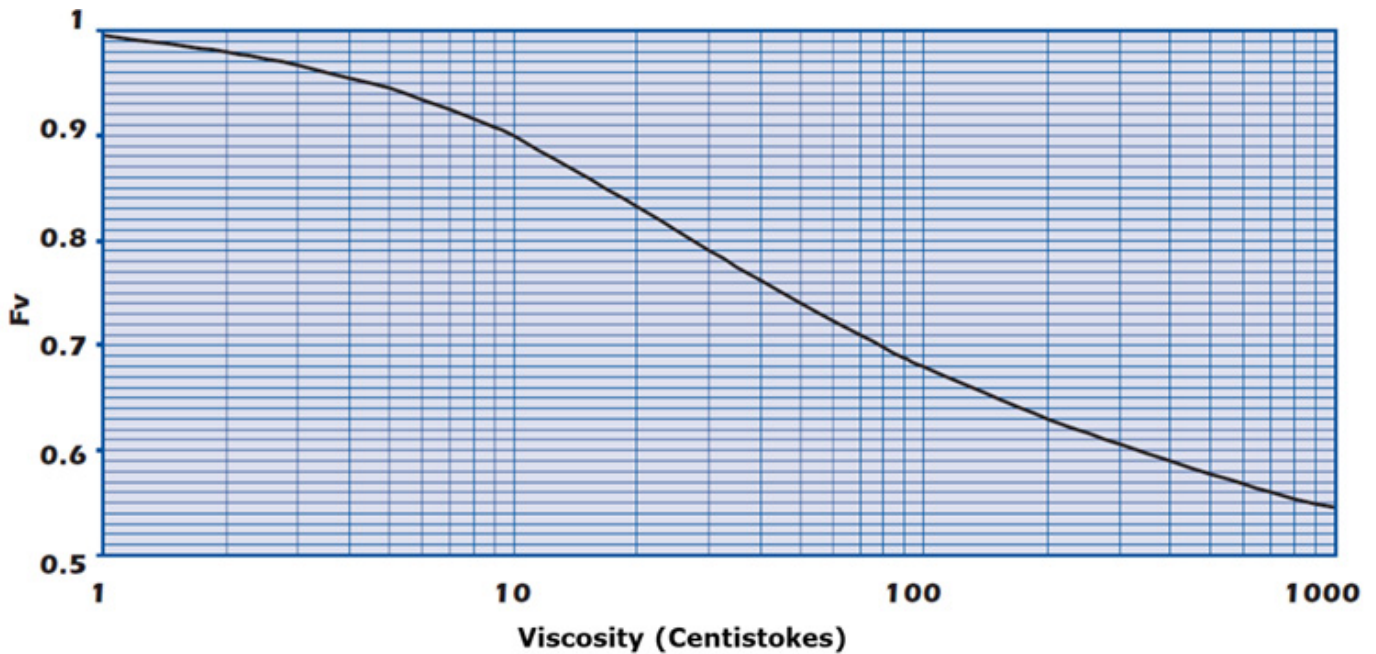

0.68 x flow coefficient = corrected flow coefficient (Kv or Cv)

Some approximate viscosities (cSt) of SAE oils at 40°C (110°F) are shown below, based on leading oil manufacturers published data.

For the selection of valves for more viscous fluids than water the following must be calculated.

Viscosity: Find the viscosity of the fluid in which the valve is to operate. The viscosity is normally expressed in centistokes. Where ISO oil is used, the grade number is also the viscosity eg ISO VG46 is 46 centistokes at 40°C (104°F).

<b>Cv</b>		8	16	31	129	96	242	378	851	1513				

### Pressure Drop

The G valve is designed to produce minimal pressure drop. The normal recommendation when determining the size of an AMOT G valve is a pressure drop between 0.01 and 0.3 bar (0.15 and 4.4 psi).

**Note:** For sea water, the valve should be sized for a pressure drop between 0.01 and 0.1 bar (0.15 and 4.4 psi).

**Note:** Kv and Cv values are applicable to 90° rotor versions only.

Kv is the flow coefficient in metric units. It is defined as the flow rate in cubic meters per hour (m<sup>3</sup>/h) of water at a temperature of 16° celsius with a pressure drop across the valve of 1 bar. Cv is the imperial coefficient. It is defined as the flow rate in US Gallons per minute [gpm] of water at a temperature of 60° fahrenheit with a pressure drop across the valve of 1 psi. (Kv = 0.865 Cv / Cv = 1.156 Kv)

The basic formula to determine the Kv of a valve is:

$$Kv = Q \sqrt{\frac{SG}{Dp}}$$

Q = Flow (m<sup>3</sup>/h)  
 Dp = Pressure drop (bar)  
 SG = Specific gravity of fluid  
 Kv = Valve flow coefficient

There are two other ways that this formula can be used to find the flow in m<sup>3</sup>/h or pressure drop of a valve in bar:

$$Q = Kv \sqrt{\frac{Dp}{SG}} \quad Dp = \left[ \frac{Q}{Kv} \right]^2 SG$$

The basic formula to determine the Cv of a valve is:

$$Cv = Q \sqrt{\frac{SG}{Dp}}$$

Q = Flow (US gallons/min)  
 Dp = Pressure drop (psi)  
 SG = Specific gravity of fluid  
 Cv = Valve flow coefficient

There are two other ways that this formula can be used to find the flow in US gallons/minute or pressure drop of a valve in PSI:

$$Q = Cv \sqrt{\frac{Dp}{SG}} \quad Dp = \left[ \frac{Q}{Cv} \right]^2 SG$$

### Valve Bypass Flowrates

The AMOT G Valve is not a tight shutoff valve. When the standard rotor type is used in a reasonably balanced pressure system there will be some small amounts of leakage between ports. The actual amount of leakage will vary with the pressure difference between these ports.

When reduced leakage is required, the Class II rotor type should be selected, allowing for a maximum leakage of 0.5% of maximum rated flow. Consult AMOT for further information if the application is sensitive to leakage rates or if high pressure differences are likely to occur.
